# *Processing limitations on acquisition of complex wh-questions in German*

C. Jane Lutken<sup>1</sup>, Bettina Braun<sup>2</sup>, & Geraldine Legendre<sup>3</sup>

<sup>1</sup>Rutgers University, <sup>2</sup>University Konstanz, <sup>3</sup>Johns Hopkins University

# Errors as evidence

- Children make errors and we can use these errors as windows into their learning process
- “**Who/What** do you think **who** is the good fairy?”
- Q: “**How** did Lewis tell Sally **what** he picked?”
- A: Apples!

What might cause these errors?

# Errors as evidence

“How did Lewis tell Sally what he picked?” “Apples!”

“Who/What do you think who is the good fairy?”

*Superficially similar to a Wh-Scope Marking (WSM) construction used in German*

“Was glaubst Du, wer die gute Fee ist?”

*What think you, who the good fairy is?”*

# Errors as Evidence

“**How** did Lewis tell Sally **what** he picked?” “Strawberries!”

“**Who/What** do you think **who** is the good fairy?”

Potential explanations:

Temporary adoption of a German-like grammar?

Two questions in a row?

Maybe biclausal questions are just hard?

Immature processing?

What do German-speaking children do?

# Potential Explanations and Predictions

## Temporary adoption of a German-like grammar?

- Maybe German is the default and German-speaking kids will perform without error
- Maybe German speaking children will show evidence of adopting another grammar

## Two questions in a row?

- It's unclear if English-speaking children are asking two questions in a row, but German-speaking children have an aptitude for verb-placement in embedded clauses (Clahsen, 1982).
- If German speaking children are asking two monoclausal questions, it stands to reason English-speaking children would do the same.

# Potential Explanations and Predictions

## Maybe biclausal questions are just hard?

- If answering questions with extraction from embedded clauses is just hard, we should see plenty of errors from German-speaking children

## Immature processing?

- If immature processing causes errors in English-speaking children, we would expect German-speaking children to show evidence of processing errors as well.

# Study with German-speaking children

- University of Konstanz
- Data from 28 children (limited due to COVID) were examined
- Age 3;11- 6;8 (mean: 5;6) recruited and tested by native German-speakers BabySprachLabor NB *\*this age range is comparable to the child participants in Lutken et al. (2020)*
- Data from 38 adult speakers were also collected to establish a norm since these tasks are open-ended.

# Study with German-Speaking children

- Two forms of production task designed to elicit questions with extraction from the embedded clause. One with a lead in, one without.

# Study with German-Speaking children

- Two forms of comprehension task: Open ended “questions after stories”. Either WSM construction OR “how+what” questions

How did Lewis tell Sally  
what he picked?

Correct Manner: The letter!  
Distractor Manner: The TV machine!  
False Object (WSM-like): The ring!  
True Object (second question): The crown!

A cartoon illustration of a grey hippo with its mouth open, appearing to be speaking or reacting to the text.

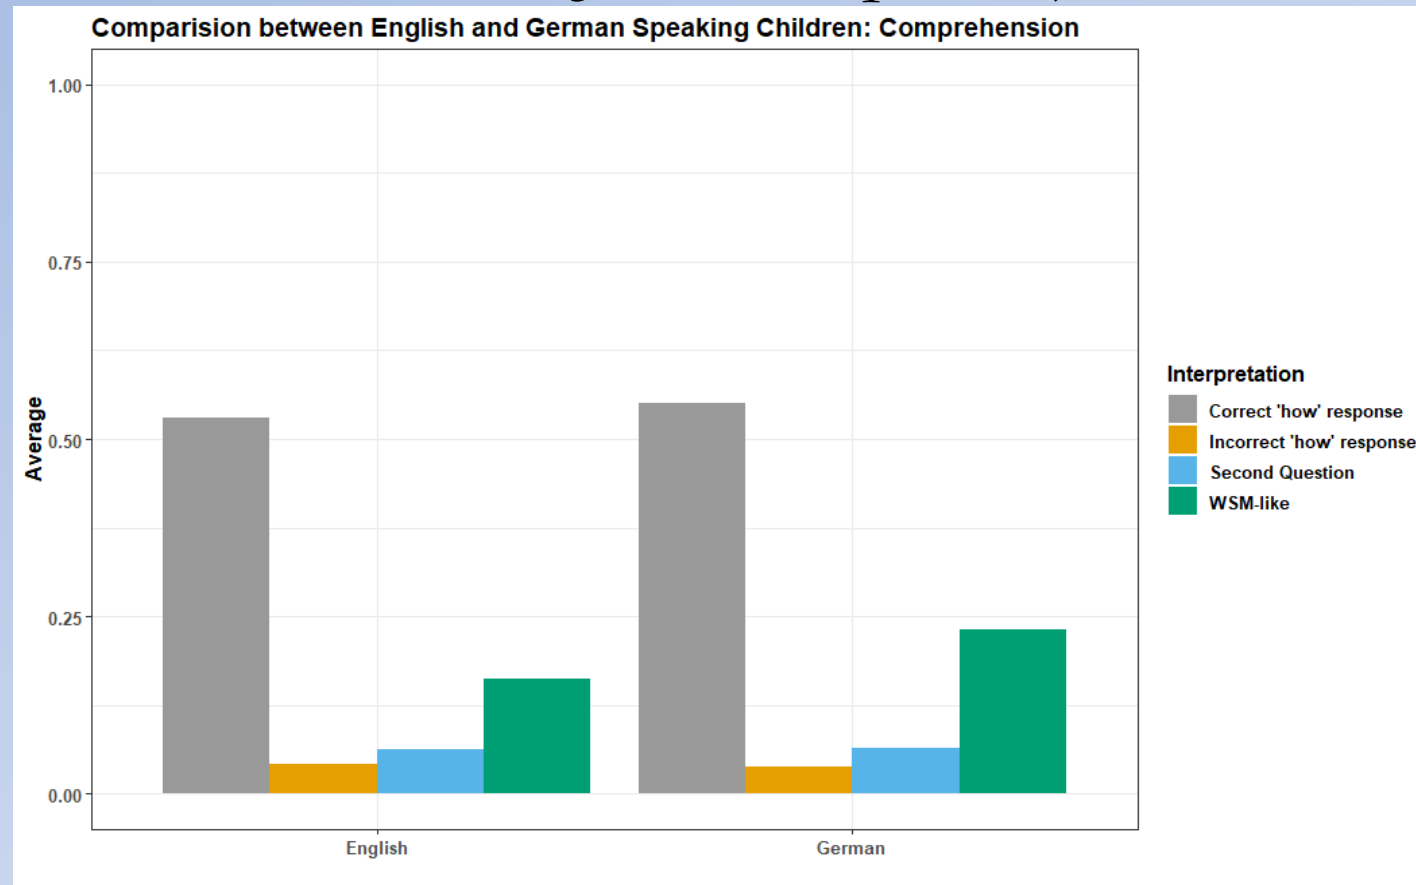

**Plus Forward and Backward  
Digit span as a measure of  
Working Memory**

# Findings: Comprehension

- In response to WSM questions (*What did Lewis tell Sally that he picked?*), 83% of responses were adult-like
- Reminiscent of English children's performance in response to LD questions in Lutken et al. (2020)

# Findings: Comprehension

- In response to questions with a medial wh-relativizer (*How did Lewis tell Sally **what** he picked?*) :

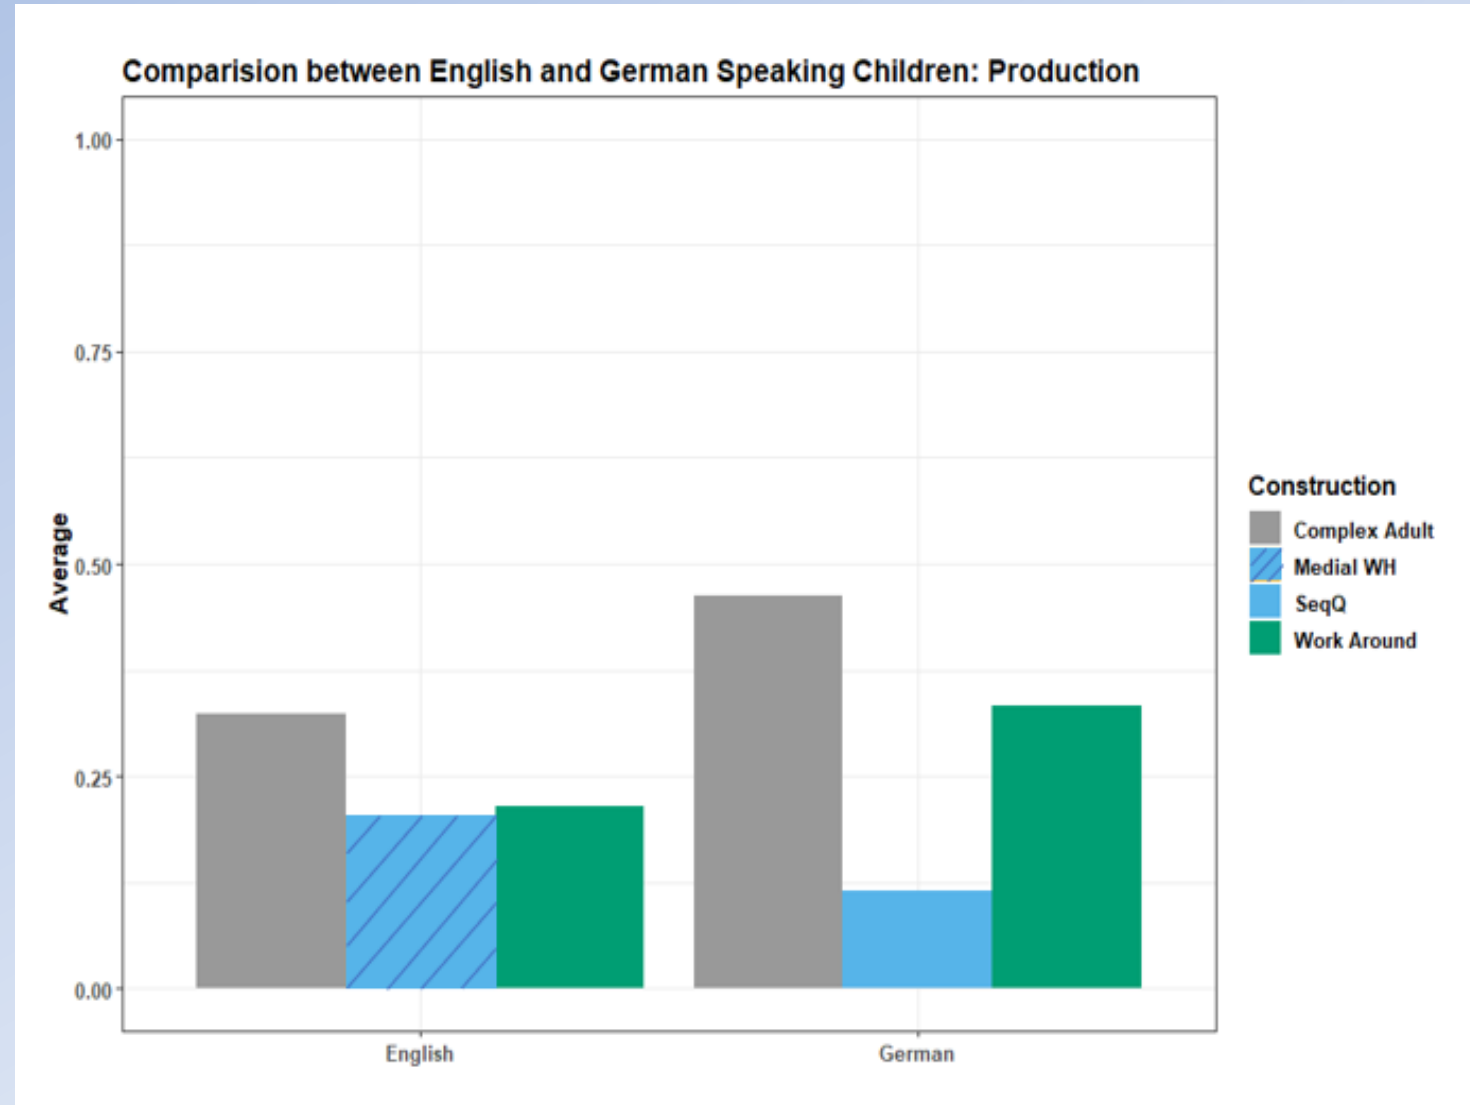

**We propose that this similar error pattern is the result of immature processing, common to English and German-speaking children**

**WM predicted adult-like performance ( $p=.01$ )**

# Findings: Production

- Mostly adult-like productions
- Many work arounds (like English-speakers)
- Used 2 questions in a row at a similar rate as English-speakers produced medial-wh...
- WM predicts disfluencies\* in productions ( $p = .05$ )

\*Disfluencies measured a la  
McDaniel, McKee & Garrett, 2010

# Study with German-speaking children

 **Temporary adoption of alternative grammar?**

- No evidence they adopt an alternative grammar

 **Two monoclausal questions in a row?**

- About 11% of productions were two questions in a row, suggesting we'd expect some productions like that from English-speakers as well

# Study with German-speaking children

## Maybe biclausal questions are just hard?

- German speaking children performed extremely well answering WSM questions
- Made mistakes in response to questions with medial wh-relativizers

## Immature processing?

- We saw strikingly similar errors in comprehension to English-speaking kids
- We saw many disfluencies in German-speaking kids' productions, though few outright errors
- WM predicted adult-like comprehension AND disfluencies in production
